ABSTRACT

In a PDA, a ROM stores beforehand a character code for specifying each character in a text and character shape data corresponding to the character code in a correlated manner while a RAM stores an image code for specifying a registered image and registered image data corresponding to the image code in a correlated manner according to registration processing by a user. Based on digitized document data containing a series of a character code, text attribute data, and an image code, a CPU transforms the registered image to be displayed according to the text attribute data and then causes an LCD to output the corresponding text and registered image simultaneously.
